

Executive Summary

This project analyzed 23,486 customer reviews from a women's clothing e-commerce company to better understand customer satisfaction and identify areas where the business can improve. Before carrying out the analysis, the dataset was cleaned by checking for missing values, removing duplicate records where necessary, and ensuring that all data was in the correct format.

Overall, customer feedback was positive. The products received an average rating of 4.20 out of 5, and 82.24% of customers recommended the products they purchased. These results suggest that most customers were satisfied with their shopping experience.

The analysis also showed that some product categories performed better than others. Dresses stood out as the category with the highest number of recommendations and the highest positive feedback from customers. This suggests that customers not only enjoyed these products but also found the reviews helpful when making purchasing decisions. In addition, the Tops department received the largest number of customer reviews, indicating high customer interest and engagement.

Another important finding was the strong relationship between customer ratings and recommendations. Customers who gave higher ratings were far more likely to recommend the products, showing that positive experiences directly influence customer loyalty and word-of-mouth recommendations.

Based on these findings, the company should focus on improving the lower-rated product categories by carefully reviewing customer comments to identify common concerns, such as quality, fit, or design. Addressing these issues can help improve customer satisfaction over time. At the same time, the company should continue promoting high-performing categories like Dresses, as these products already have strong customer support and can help drive more sales.

Regularly reviewing customer feedback will also help the company stay informed about customer needs, respond to issues more quickly, and make better business decisions.
